TED4STL: Trend-Error Decomposition for Self-Supervised Time Series Learning in Multivariate Forecasting Task

Technical Report

Anonymous Author(s)

Abstract

Self-Supervised Learning (SSL) has become a powerful paradigm in Artificial Intelligence, enabling the training of machine learning models using unlabeled data. However, in time series forecasting, SSL models are generally less effective than supervised models due to the complexity of temporal patterns, including trends, seasonality, and noise. To address this, we experiment a straightforward data-centric approach that decomposes time series into two additive components, and we investigate whether a similar decomposition can improve the performance of SSL models. We introduce TED4STL (Trend-Error Decomposition for Self-supervised Time-series Learning), a pipeline that applies time series decomposition to SSL architectures. This pipeline is adapted to four SSL forecasting models and evaluated on ten benchmark datasets. Our results demonstrate that time series decomposition significantly improves the accuracy of SSL models in forecasting tasks, narrowing the gap with state-of-the-art supervised models. In short-term prediction, it enables SSL models to perform in general better than supervised ones.

Keywords

Self-Supervised Learning, Time Series Forecasting, Time Series Decomposition

1 Experimental Evaluation

The following sections present supplementary results in the form of tables, offering additional insights that complement and enrich the main findings.

Settings. The experiments have been performed on a Workstation with an NVIDIA L40S GPU with 48 GB of VRAM, 256 GB of RAM, and a dual AMD EPYC 9254 24-Core Processor. According to the literature in the field, the predictions are computed via direct multi-step forecasting [1]. Moreover, we used the hyperparameters defined for each model as indicated in the original papers. The only exception was the moving average, whose kernel size we determined through a grid search, exploring the values $\{9, 25, 64, 96, 128, 224\}$ on the validation set.

Datasets. We conducted experiments on ten widely used in the literature real-world datasets in the field of time series forecasting:

(1) **ETT (Electricity Transformer Temperature)**[1]: It consists of two hourly sampled datasets (ETTh1/ETTh2) and two 15-minute-sampled datasets (ETTm1/ETTm2) of electricity transformer temperatures, containing features such as oil temperature and load.
(2) **Exchange**[2]: It collects the daily exchange rates of 8 countries from 1990 to 2016.
(3) **WTH**[3]: This dataset contains hourly observations of 12 climate-related variables, including temperature, humidity, wind speed, and solar radiation, across nearly 1,600 locations in the United States.
(4) **Electricity**[4]: This dataset consists of hourly electricity consumption data from 321 residential and industrial clients over the period from 2012 to 2014.
(5) **Traffic**[5]: It is a dataset containing 48 months of hourly road occupancy rates, gathered between 2015 and 2016 by 862 sensors from the California Department of Transportation in the San Francisco Bay area.
(6) **Weather**[6]: It includes 21 indicators of weather, such as air temperature, and humidity.
(7) **ILI (Influenza-like Illness)**[7]: It contains weekly reports from the Centers for Disease Control and Prevention (CDC) in the U.S., tracking the number of patients with influenza-like illness (ILI) from 1997 to 2022.

Table 1 shows a quantitative description of the datasets regarding the number of signals, series, timestamps and granularity.

Supervised Forecasting Baselines. We selected PatchTST [2] and DLinear [3] as supervised forecasting models. PatchTST is a SOTA transformer-based model; DLinear achieves competitive accuracy through moving average decomposition and a single linear layer.

1.1 Forecasting Evaluation

The effectiveness of our decomposition pipeline is evaluated using Mean Squared Error (MSE) and Mean Absolute Error (MAE), defined as $\text{MSE} = \frac{1}{N}\sum_{i=1}^{N}(y_i - \hat{y}_i)^2$ and $\text{MAE} = \frac{1}{N}\sum_{i=1}^{N}|y_i - \hat{y}_i|$, where y and $\hat{y}$ denote the true and predicted values, respectively. experiment measures the forecasting error of SSL models with and without TED4STL across five prediction lengths, which vary by dataset and are chosen according to the literature for SSL forecasting models.

List of Tables. . The following list provides an overview of the tables included in this document.

- **Table 2**: MSE values for each dataset and prediction length, evaluated using grid search with a moving average kernel size.
- **Table 3**: MAE values for each dataset and prediction length, evaluated using grid search with a moving average kernel size.
- **Table 4**: Percentage improvements for each dataset in terms of MAE and MSE.
- **Table 5**: Results for TS2Vec with different kernel size K.
- **Table 6**: Results for SimTS with different kernel size K.
- **Table 7**: Results for CoST with different kernel size K.
- **Table 8**: Results for MaskAE with different kernel size K.
- **Table 9**: Short-term forecasting results across all models and baselines with a fixed kernel size of 25.

1.2 Ablation Study

To understand the contribution of the time series decomposition, we run the selected SSL models again using the embeddings generated by the trend and the error components of the decomposition pipeline alone. In this case, we selected the same kernel size (25 timestamps) for the moving average in all experiments. The findings do not change considering different kernel sizes.

List of Tables. . The following list provides an overview of the tables included in this document.

- **Table 10a**: Ablation for TS2Vec and SimTS in terms of MSE.
- **Table 10b**: Ablation for TS2Vec and SimTS in terms of MAE.
- **Table 11a**: Ablation for CoST and MaskAE in terms of MSE.
- **Table 11b**: Ablation for CoST and MaslAE in terms of MAE.
